

How to connect capacitors to frequency dividers

Overview

But just like resistive circuits, a capacitive voltage divider network is not affected by changes in the supply frequency even though they use capacitors, which are reactive elements, as each capacitor in the series chain is affected equally by changes in supply frequency. This ability of a capacitor to oppose or react against current flow by storing charge on its plates is called reactance, and as this reactance relates to a capacitor it is therefore called Capacitive Reactance (X_c), and like. When a fully discharged capacitor is connected across a DC supply such as a battery or power supply, the reactance of the capacitor is initially extremely low and maximum circuit current. Capacitance, however is not the only factor that determines capacitive reactance. If the applied alternating current is at a low frequency, the reactance has more time to build-up for a given RC time constant. Now if we connect the capacitor to an AC (alternating current) supply which is continually reversing polarity, the effect on the capacitor is that its plates are continuously charging and.

DC voltage divider using capacitors

The reactive part for a capacitor depends on frequency. Look it up to find $X_c = 1/j \cdot (2 \cdot \pi \cdot \text{Frequency} \cdot \text{Capacitance})$, and the "j" down there ends up giving it a minus sign. The lower the frequency, the bigger X_c it gets, until at ZERO frequency, we have arrived at DC, and the impedance is infinite!
