Overview

An innovative image analysis technique is proposed to process real solar cell pictures, identify grains and grain boundaries in polycrystalline silicon, and finally generate finite element meshes. Using a modified intrinsic. Photovoltaics (PVs) based on silicon semiconductors is the most growing technology in the world. 2.1. Image analysis of solar cells The majority of produced solar cells are made of either mono or polycrystalline silicon. The material microstructure has a role on the electrical properties. For the numerical simulation of transgranular and intergranular cracking in polycrystalline silicon, a 2D plane stress model is considered. The principle of virtual work reads: $\delta U = \delta W$. A model problem consisting of 4 grains (lateral size of about 1 cm) is analyzed under plane stress conditions with a typical thickness of solar cells equal to 0.166 mm. Three different loading cases are considered. A computational framework for the simulation of intergranular and transgranular cracking in polycrystalline silicon solar cells has been proposed in the present work. To.
